

Wiring principle of wire core temperature sensing terminal box

Overview

Wiring typically involves connecting the thermocouple sensor to the input terminals of the transmitter, and connecting the loop power supply and receiving device (e., PLC analog input) in series with the output terminals. Refer to the manufacturer's manual for polarity and. A temperature transmitter is commonly used to convert the output signal from temperature sensors like RTDs (Resistance Temperature Detectors) or thermocouples into a standard 4-20 mA current signal that can be read by a PLC or control system. While the Hot Junction refers to the tip of the thermocouple that will be exposed to the heat source of interest, the cold junction refers to the thermocouple wire connections that happen right at the. They work on the principle of the Seebeck effect, which is the generation of a voltage when two dissimilar metals are connected at different temperatures. The voltage produced is proportional to the temperature difference between the hot and cold junctions of the thermocouple.
